
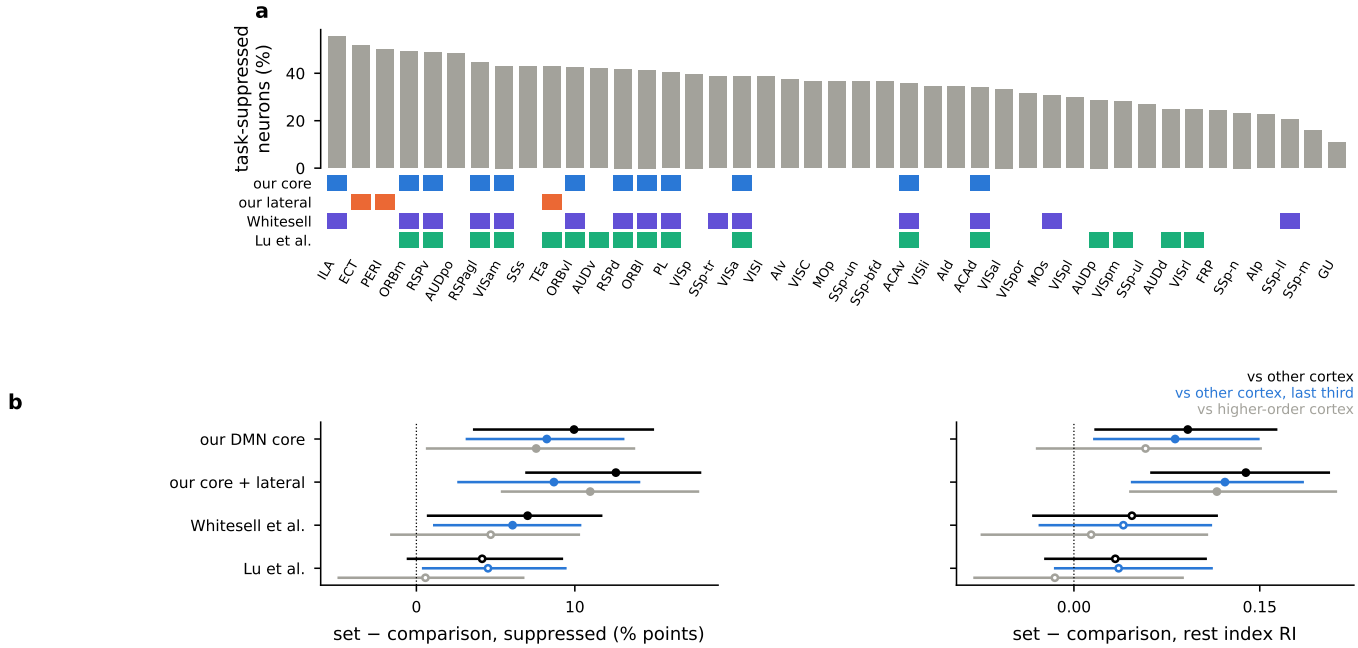

Figure S1: a Task-suppressed neurons per cortical region relative to the grey screen (as Fig. 3a, grey bars), with region membership in four DMN definitions underneath. Whitesell et al. (2021): cortical regions with >50% of voxels in the core DMN mask of mouse rsfMRI group ICA, registered to the Allen CCFv3 (ACA, PL, ILA, ORB, RSP, VISa, VISam, SSp-tr, SSp-ll, MOs). They do not include TEa, ECT or PERI (our lateral extension), which lie in their separate lateral cortical network. **b** Each definition minus other cortex (black), the same against only the last third of trials (blue), and minus higher-order cortex only (grey): 95% mouse-bootstrap CI; filled markers, region-permutation $p < 0.05$. The Whitesell set is weaker than ours because it adds the task-driven SSp-tr, SSp-ll and MOs and leaves out TEa, ECT and PERI.
