

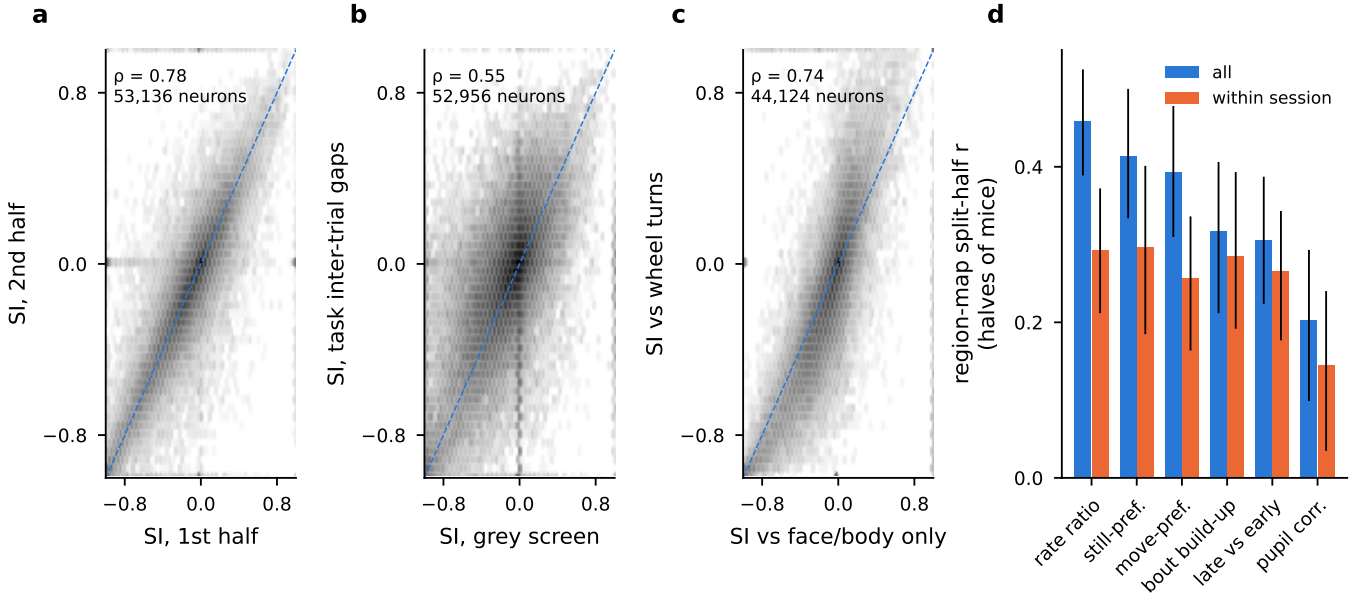

Figure 3: Stillness preference is reproducible within recordings; region differences are reproducible but modest. **a** Stillness index SI = (still − moving)/(still + moving) of each neuron in the first vs second half of the grey screen. **b** SI on the grey screen vs in the inter-trial gaps of the task, a second behavioural context recorded earlier in the session. **c** SI computed against face/body movements without wheel turns vs against wheel turns. **d** Reliability of region maps over animals: Spearman r between region means from two random halves of the mice (200 splits, median and 5–95% range), from raw neuron values (blue) and after subtracting each session's mean (orange). Regions with ≥20 neurons from ≥3 mice. Region within session explains 13% of neuron variance in the rate ratio (label shuffle 4%), session 6%.
