

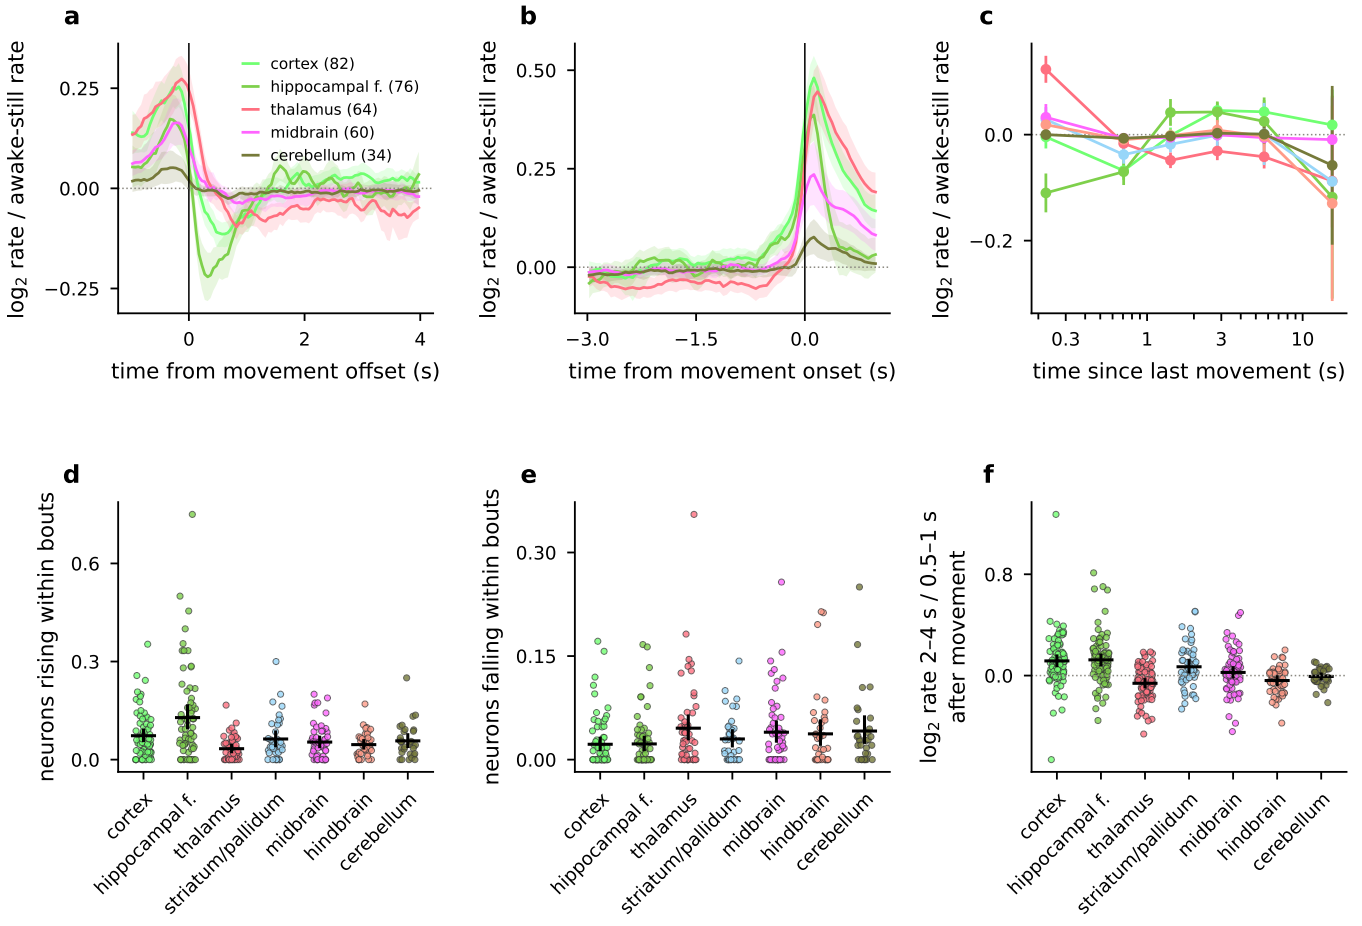

Figure 4: Stillness is graded: firing dips after movement ends, then thalamus keeps falling while cortex and hippocampus recover. **a** Population rate around the end of a movement that starts an awake-still bout of $\geq$4 s, relative to the awake-still rate; mean over mice (number in legend) and bootstrap 95% CI, 250 ms smoothing. **b** The same around movement onset after $\geq$3 s of awake stillness. **c** Rate in awake-still bins by time since the last movement (all bouts), mean over mice $\pm$ 1.96 s.e.m.; colours as in a, plus striatum/pallidum and hindbrain. **d** Fraction of neurons whose rate rises from the first 0.5 s to 2–4 s within $\geq$4 s bouts (Wilcoxon over bouts, $p < 0.01$); dots are mice. **e** Fraction of neurons whose rate falls. **f** Rate 2–4 s vs 0.5–1 s after the last movement, per mouse.
