
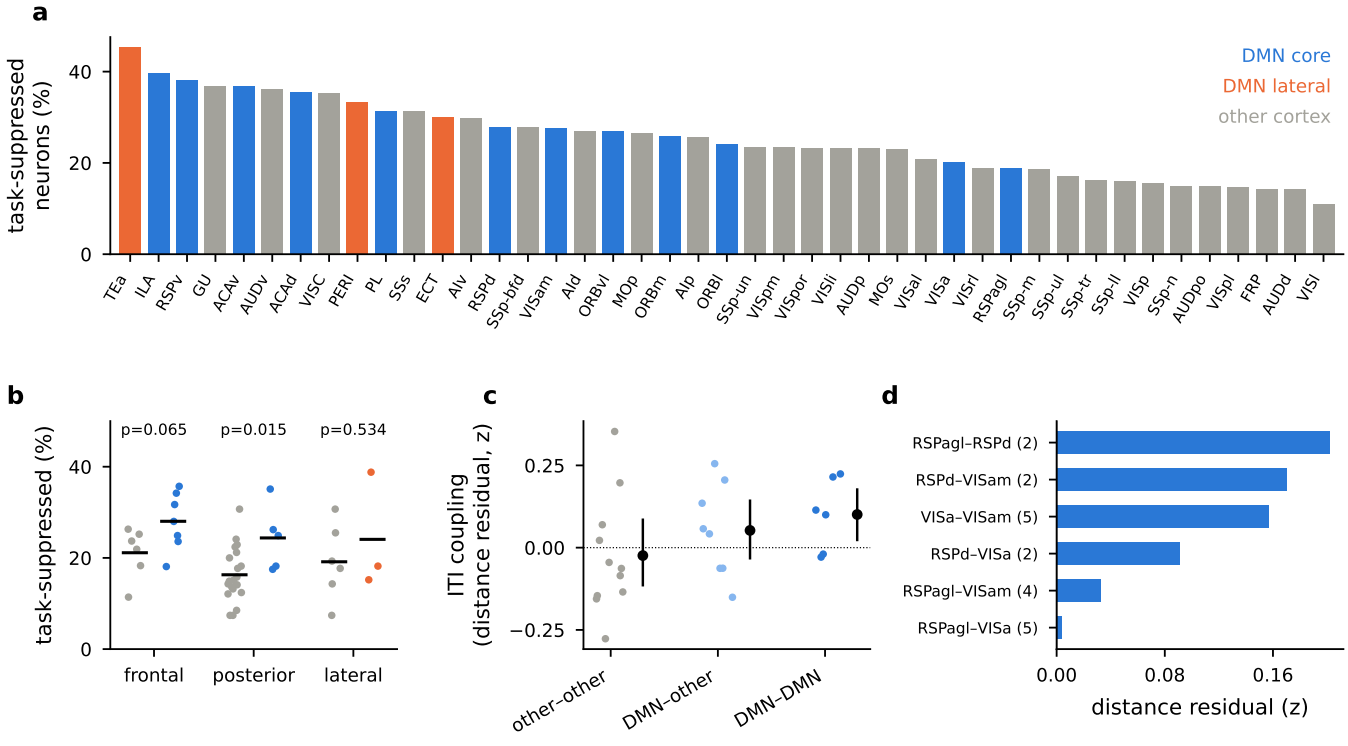

Figure 1: **a** BWM Neuropixels, 419 sessions, 137 mice: percentage of neurons per cortical region (Beryl) significantly suppressed during the task (stimulus, movement and feedback windows) relative to still inter-trial rest. Blue, DMN core (ACA, PL, ILA, ORB, RSP, VISa, VISam); orange, DMN lateral (TEa, ECT, PERI); grey, other cortex. **b** Same measure under strict stillness, DMN regions vs non-DMN neighbours within frontal (vs MOs, MOp, FRP, AI), posterior (vs SSp, AUD, VIS) and lateral (vs AUD, VISC, GU) cortex; dots are regions, bars means, region-permutation p. **c** Mesoscope (45 sessions, 11 mice): correlation of region-averaged calcium activity in still inter-trial bins (1 s, wheel/lick/motion-energy regressed), as residual from the distance-matched mean; dots are mice, black mean and 95% mouse-bootstrap CI. **d** Mean residual coupling per DMN region pair (number of mice in brackets); the DMN–DMN excess is carried by VISa–VISam and RSP pairs.
