Neural correlates of stillness: replication in Allen Institute Neuropixels data

Analysis report

ibl · 2026-10-30T14:56:37Z

Summary

The uploaded manuscript reports neural correlates of stillness in the IBL Brain-Wide Map: 53,136 neurons from 389 sessions and 130 mice, recorded during the passive grey screen after the task, with "moving" defined from wheel, lick and face motion in 50 ms bins. Its main findings are lower firing in stillness (log2 rate ratio -0.43, 129 of 130 mice), a stable minority of still-preferring neurons (about 15%, against about 40% movement-preferring), the strongest movement modulation in brainstem and thalamus, and a rise in firing 0.3 to 0.5 s before movement onset.

This report tests those findings in two independent public datasets held on the OCS platform: the Allen Institute Visual Behavior Neuropixels dataset (DANDI 000713; mice on a running wheel, grey screen after an active change-detection task, running speed and pupil area available) and the Allen Visual Coding Neuropixels dataset (passive viewing, spontaneous grey-screen blocks, running speed only). Spike times are the depositors' sorted units as held on the platform, already restricted to units the Allen Institute labels "good" for Visual Behavior. Unit brain regions are the deposits' Allen CCF labels, grouped into Cosmos divisions.

Neither Allen dataset has face video, and licks are not logged on the grey screen, so movement here means running only. This is the main methodological difference from the IBL analysis.

Question

Do the IBL neural correlates of stillness (lower firing in stillness, a stable still-preferring minority, division-specific modulation and a pre-movement rise in firing) replicate in independent mice, rigs and labs, using the same pipeline applied to Allen Neuropixels grey-screen recordings?

Methods and analyses

1. Session selection and stillness screen

Allen Visual Behavior: a first cohort of 12 mice was drawn at random (one session each) from mice whose probes reached thalamus and midbrain; then all remaining sessions (138 sessions, 78 mice) were split by mouse into four batches and processed in parallel with identical stored code. A separate pilot mouse (599294) used to develop the pipeline was excluded from all summaries. Allen Visual Coding: 10 sessions were screened. The analysis window was the post-task grey screen for Visual

Behavior (about 289 s per session) and the longest genuine spontaneous presentation from each Visual Coding session's per-presentation stimulus table (about 5 min). The platform's block marker for Visual Coding spans 143 min including stimuli and was not used; spike, running and stimulus clocks were checked to agree. Every session was first labelled bin by bin (see next analysis) and included only if it had at least 10 awake-still and at least 10 moving 0.5 s epochs. Selection used behaviour only, never neural effect sizes.

Script: scripts.md, part 3 (stillness_pipeline.py: state_bins, epochs); batch screen tables in data_screening.csv

2. State labelling (moving, awake-still)

The grey-screen window was divided into 50 ms bins. A bin was 'moving' if the maximum absolute running speed in it exceeded 2 cm/s (bins without a running sample took the nearest bin's label). 'Still' bins were non-moving bins that were also not adjacent to a moving bin (one-bin margin on each side). Still bins counted as 'awake-still' only if they lay within 30 s of the last movement (time since movement measured from bin centres, counted from the window start before the first movement) and, for Visual Behavior, if the mean pupil area in the bin (blinks removed) was not below the 10th percentile of pupil area during the task. Bins with no pupil sample were not gated. Visual Coding has no pupil data, so only the 30 s rule applied, as the manuscript does for sessions without pupil tracking.

Script: scripts.md, part 3a: state_bins()

3. Per-neuron rate ratio and state preference

Spikes from every probe of a session were binned into the same 50 ms grid. For each unit, the rate in all awake-still bins and in all moving bins was computed, and the log2 rate ratio was log2((rate_still + 0.1) / (rate_moving + 0.1)), with a 0.1 Hz pseudocount; negative values mean lower firing in stillness. For the preference test, 0.5 s epochs (10 consecutive bins entirely inside one state, at most one epoch starting per 2 s window, non-overlapping) were extracted for each state; each epoch's spike count was converted to a rate and still versus moving epochs were compared with Welch's t-test. A unit was still-preferring if $p < 0.01$ and its mean still rate exceeded its moving rate, movement-preferring if $p < 0.01$ in the other direction. Only units with a grey-screen rate of at least 0.5 Hz were kept for all statistics (63,399 of 84,661 units). No further isolation cut was applied. Unit regions were mapped to Cosmos divisions with the Allen CCF hierarchy; labels that are not Allen acronyms (for example 'none') were assigned to 'root'.

Script: scripts.md, part 3a: neuron_stats(), epochs(); part 3b: run_mouse()

4. Mouse-level summary and statistics

Per-session values (mean log2 ratio over kept neurons; fractions of still- and movement-preferring neurons) were averaged within mouse so that each mouse counts once (14 mice contributed two sessions). Confidence intervals are 95% percentile bootstrap intervals over mice (10,000 resamples, seed 20261030). Tests are two-sided Wilcoxon signed-rank tests over mice. The dependence of detection on still time was assessed with a Spearman correlation between each session's still-preferring fraction and its number of still epochs.

Script: scripts.md, part 1: stillness_stats.py (recomputes every number from data_neurons.csv)

5. Brain-division breakdown

Within each session, the mean log2 ratio was computed for each Cosmos division holding at least 20 kept neurons, then averaged within mouse. Divisions are reported where enough mice contributed: midbrain (MB), thalamus (TH), hippocampal formation (HPF) and isocortex. Units labelled only 'root' were excluded (one Visual Behavior session has 811 of 1,217 units unlabelled, and another 1,205 of 1,648).

Script: scripts.md, part 1: stillness_stats.py (division section)

6. Pre-movement firing

Still-to-moving transitions were taken as the first moving bin preceded by at least 1 s of awake stillness. For each session, every kept neuron's rate was averaged over transitions in a window from -2.0 to +1.0 s (50 ms bins), then averaged across neurons and expressed as % change from the mean over -2.0 to -1.0 s. Sessions with fewer than 5 transitions were excluded (the first 4 mice were stored already normalised). Curves were averaged within mouse. The rise onset is the earliest time from which the bootstrap CI of the mouse mean stays above zero up to movement onset.

Script: scripts.md, part 3b: premove(); curves in data_premovement_curves_pct.csv

Results

Session selection and stillness screen

44 of 150 Visual Behavior sessions (30 mice) and 4 of 10 Visual Coding sessions (4 mice) passed. Almost all Visual Behavior exclusions were mice that ran through the whole grey screen (for example, 21 of 35 sessions in one batch); a few were excluded because the mouse never moved. Five Visual Coding sessions failed because the mouse barely moved, and one had no stimulus table or running data on the platform. Included sessions had short stillness: 0.15 to 2.8 min of awake stillness, with most under 1 min.

State labelling (moving, awake-still)

The pupil gate removed little or no still time in most sessions, as expected for short still bouts immediately after the task. In the pilot mouse, moving the running threshold between 1 and 5 cm/s changed the mean log2 ratio only between -0.13 and -0.05 and the still-preferring fraction between 13% and 14%.

Per-neuron rate ratio and state preference

Session level: the mean log2 ratio over kept neurons was negative in 47 of 48 sessions (the exception, +0.03, was one of two sessions of a mouse whose mouse-level mean is negative). Pooled over all kept neurons, 12.2% were still-preferring and 24.2% movement-preferring.

Mouse-level summary and statistics

Firing was lower in stillness in all 34 mice: mean log2 ratio -0.128 [-0.155, -0.101], Wilcoxon p = 1.2e-10 (Visual Behavior -0.122 [-0.151, -0.095], 30/30 mice; Visual Coding -0.167 [-0.235, -0.098], 4/4). Still-preferring neurons made up 11.9% [10.6, 13.4] per mouse and movement-preferring 24.1% [22.5, 25.7]; movement-preferring outnumbered still-preferring in all 34 mice. The still-preferring fraction rose with still time (Spearman rho = 0.71, p = 6.7e-08, 44 sessions); the 16 sessions with at least 50 still epochs averaged 15.4% still-preferring and 27.9% movement-preferring. The mean log2 ratio did not depend on still time (rho = -0.15, p = 0.35).

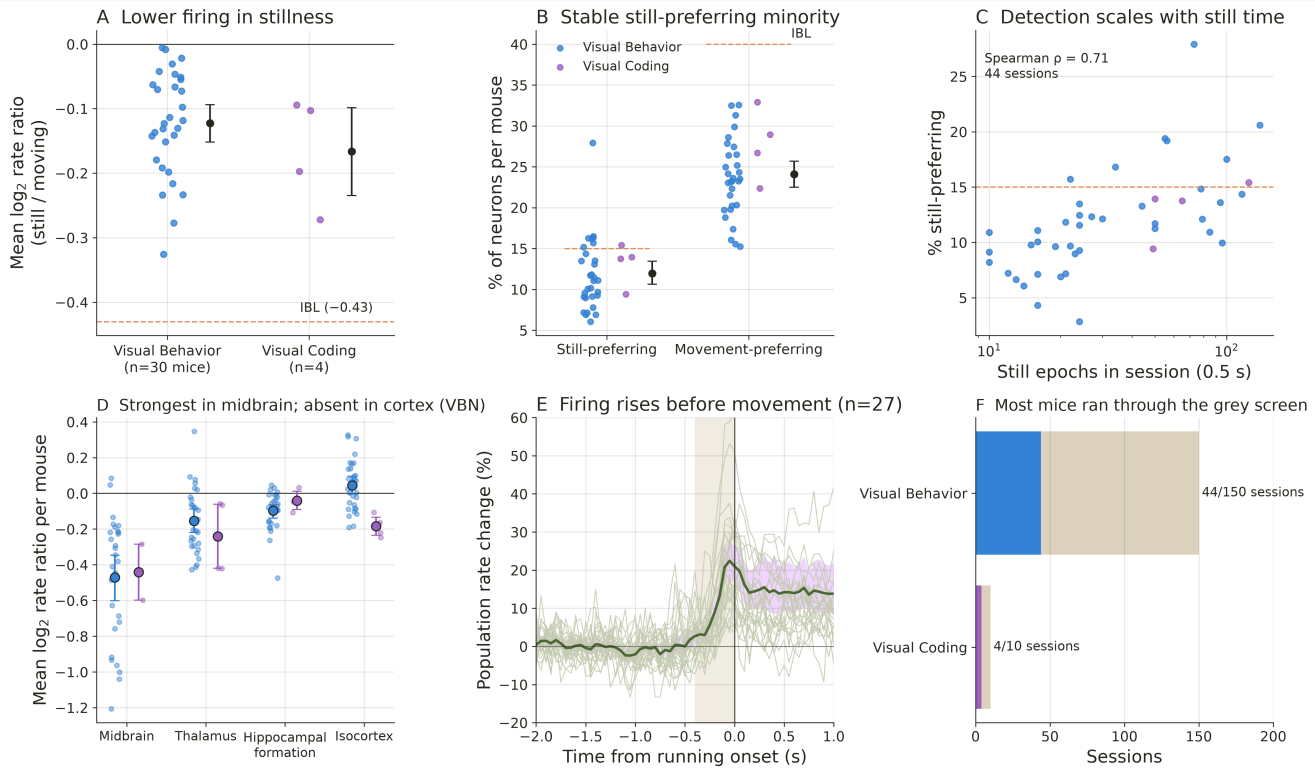

Brain-division breakdown

Visual Behavior: midbrain -0.47 [-0.60, -0.35], 26/28 mice below zero, p = 3.7e-08; thalamus -0.16 [-0.22, -0.09], 23/29, p = 1.6e-04; hippocampal formation -0.10 [-0.14, -0.06], 25/29, p = 2.4e-06; isocortex +0.04 [-0.01, +0.10], 12/30, p = 0.16. Visual Coding (4 mice, no tests): isocortex -0.18 [-0.23, -0.13] in 4/4 mice, thalamus -0.24 in 4/4, midbrain -0.44 (2 mice), hippocampal formation -0.04.

Pre-movement firing

27 mice had usable curves. Population firing rose from about -0.4 s before running onset; the mean change from -0.5 to -0.05 s was +6.6%, positive in 25 of 27 mice (Wilcoxon p = 2.1e-07). The earlier

window (-1.0 to -0.5 s) showed no change (-0.7%, p = 0.20).

Replication of the neural correlates of stillness in Allen Neuropixels data (30 Visual Behavior and 4 Visual Coding mice). Each mouse weighted once; error bars, 95% bootstrap CIs over mice; dashed lines, IBL values from the manuscript. A, mean log2 rate ratio (still/moving) per mouse. B, percentage of still- and movement-preferring neurons per mouse (Welch p < 0.01, 0.5 s epochs). C, still-preferring fraction per session against the number of still epochs. D, mean log2 ratio per mouse by Cosmos division (at least 20 neurons per session). E, population rate change around still-to-running onsets, as % of the -2 to -1 s baseline; thin lines, mice; band, 95% CI; shaded region, -0.4 to 0 s. F, sessions screened and included.

Insights

The direction of every core IBL finding replicates in independent mice from a different lab and rig. Firing is lower in stillness in all 34 mice, firing rises before movement starts on the same timescale, and the still-preferring population is present in every mouse at about the IBL proportion once a session has enough stillness to detect it (15.4% in sessions with at least 50 still epochs, against 15% in IBL).

The magnitudes are smaller. The overall rate ratio (-0.13) is about a third of the IBL value (-0.43), and movement-preferring neurons are fewer (24% against 40%). The most likely reason is the movement definition. IBL's moving state is dominated by face and body movement, while here only running counts. Whisking, licking and other orofacial movements therefore fall inside "still" bins, which dilutes the contrast. Short still periods also limit the per-neuron test, as panel C shows directly.

The division pattern matches IBL's ordering where comparable: midbrain is the most movement-modulated division, followed by thalamus, with a weaker hippocampal effect. Isocortex is the exception. It shows no stillness effect in Visual Behavior mice but a clear one in all four Visual Coding mice. Those datasets differ in context (post-task grey screen after water-restricted change detection versus naive passive viewing). The difference could also come from cortex being especially sensitive to unmeasured face movement. With 4 Visual Coding mice this is a hint, not a result.

Caveats

Exploratory and not pre-registered. The pipeline parameters were taken from the manuscript and fixed before the batches ran, but no decision rules were frozen.

Movement is running only. No face video exists for these datasets and licks are not logged on the grey screen, so "still" includes orofacial movement. Running onsets are detected at a 2 cm/s threshold, which can lag the true start of movement. Some of the pre-movement rise may therefore reflect early movement below threshold.

Only 48 of 160 screened sessions qualified, because most Allen mice ran through the grey screen. Included mice are those that happened to stop, which may not represent all mice. Still periods were short (mostly under 1 min), which limits per-neuron power. Synchrony, the thalamus-pupil relation and within-bout time courses were not tested for this reason.

The Visual Coding arm has 4 mice and no pupil gate. Units are the depositors' sorted units, with only a 0.5 Hz rate cut and no extra isolation cut. Some sessions lack region labels for many units, and those units are excluded from the division analysis only. The platform marks the meaning of the Visual Behavior pupil-area stream as unconfirmed by the depositors; it affects only the drowsiness gate. The pre-movement curves of the first 4 mice were normalised at storage time; the others were normalised as described.

Next steps

1. Confirm on held-out data. Freeze decision rules (for example, rate ratio below zero in more than 75% of mice, still-preferring neurons present in most mice, a positive pre-movement change) and test them on mice not used here. 2. Test the movement-definition explanation in a dataset with face video. The Stringer lab Facemap sessions (visual cortex, imaging) would show whether cortex follows the IBL pattern once face movement counts as moving. 3. Extend the Visual Coding arm, the only Allen context without a preceding task, to test whether the cortical difference holds beyond 4 mice.
