
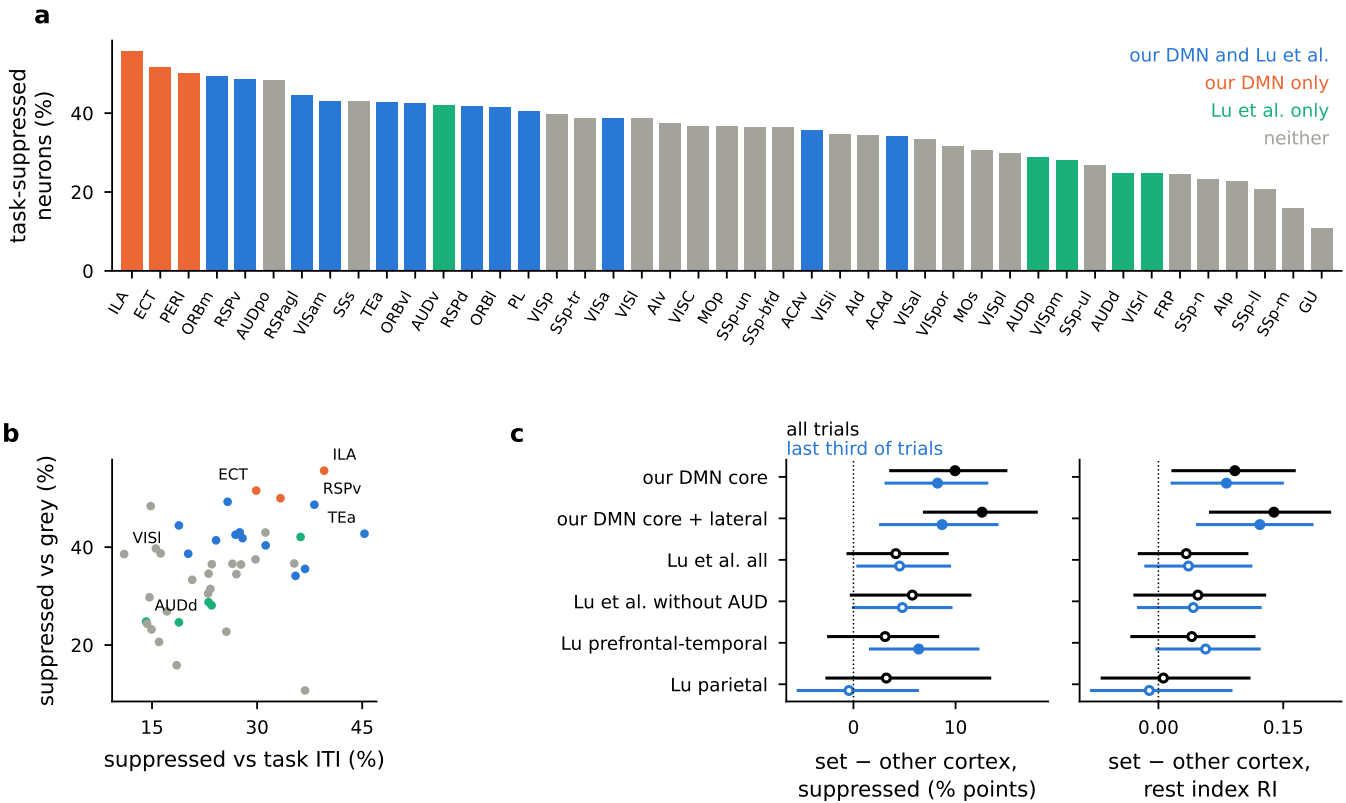

Figure 3: a Percentage of neurons per cortical region (Beryl) significantly suppressed during the task (movement onset, movement and feedback windows) relative to still 0.3 s chunks of the grey-screen period (Welch test with one chunk per 3 s, $p < 0.01$; 53,213 neurons, 395 sessions, 130 mice). Colour: membership in our mouse DMN definition (ACA, PL, ILA, ORB, RSP, VISa, VISam + TEa, ECT, PERI) and in the rat DMN of Lu et al. (2012) mapped to mouse regions (ORB, PL, ACA, AUDp/d/v, TEa, VISa, VISrl, RSP, VISam, VISpm; CA1 not shown). **b** Per region, the same measure referenced to task ITIs (earlier report) against the grey-screen reference; Spearman $\rho = 0.44$ over 43 regions. **c** Difference between each region set and all other cortex in the suppressed fraction (left) and in the continuous rest index RI = (rest − task)/(rest + task) (right), against all trials (black) or only the last third of trials, closest in time to the grey screen (blue): 95% mouse-bootstrap CI; filled markers, region-permutation $p < 0.05$. Note that 81% of neurons differ significantly between grey screen and task, so the suppressed fraction is close to the sign of RI.
